Java

Several notes about Reflection API

Overview

- reflection, introspection
- allows for
 - obtaining information about classes, fields, methods
 - creating objects
 - calling methods
- the package java.lang.reflect
- the class java.lang.Class<T>

java.lang.Class

- an instance of the class **Class** represents a class (interface, enum,...) in a running program
- primitive types also represented as instances of Class
- no constructor
- instances created automatically during loading the class code to JVM
 - classes are loaded to JVM when firstly used

3

java.lang.Class

- obtaining an instance of Class
 - getClass()
 - the method of the Object class
 - returns the class of the object on which was called
 - the class literal
 - NameOfClass.class
 - the class for the given type
 - Class.forName(String className)
 - static method
 - returns the class of the given name
 - for primitive types
 - the static attribute TYPE on the wrapper classes
 - Integer.TYPE
 - the literal class
 - int.class

java.lang.Class

- class are loaded to JVM by a classloader
 - java.lang.ClassLoader
 - the standard classloader looks up classes in CLASSPATH
 - own classloaders can be created
 - Class.forName(String className, boolean initialize, ClassLoader cl)
 - loads the class by the given classloader and returns an instance of the Class
 - getClassLoader()
 - the method of Class
 - the classloader, which loaded the class

java.lang.Class: methods

- String getName()
 - returns the name of the class
 - for primitive types returns their names
 - for array returns a string beginning with the chars '[' (number of '[' corresponds to dimension) and then an identification of the element type
 Z..boolean, B..byte, C..char, D..double, F..float, I..int, J..long, S..short,
 Lclassname..třída nebo interface

java.lang.Class: methods

- public URL getResource(String name)
- public InputStream getResourceAsStream(String name)
 - reads a resource
 - image,, anything
 - data loaded by a classloader => loading by the same rules as loading classes
 - a name of the resource ~ a hierarchical name as of classes
 - dots replaced by '/'

java.lang.Class: methods

```
• is... methods
 - boolean isEnum()
 - boolean isInterface()
• get... methods
 - Field[] getFields()
 - Method[] getMethods()
 - Constructor[] getConstructors()
```

Usage of Reflection API

- information about code
- dynamic loading
- plugins
- proxy classes

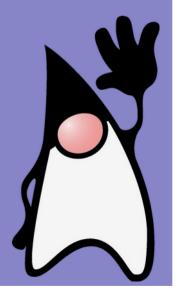

• ...

• more details in NPRG021

Java

jar

Overview

- creating archives composed of .class files
- JAR ~ Java Archive
- file
 - extension .jar
 - format 7IP
 - file META-INF/MANIFEST.MF
 - description of the content
- usage distribution of software
 - CLASSPATH can contain .jar files
 - .jar files can be directly executed
- can contain also other files than .class files
 - images
 - audio
 - anything else

Usage

creating an archive

```
jar cf file.jar *.class
```

- creates the file.jar with all .class files
- adds the MANIFEST.MF file to it
 jar cmf manifest file.jar *.class
- creates the file.jar with the given MANIFEST file
 jar cf0 soubor.jar *.class
- no compression
- see documentation for other parameters
- API for working with jar files
 - java.util.jar, java.util.zip

MANIFEST.MF file

- list of tuples
 - name: value
 - inspired by the standard RFC822
- tuples can be grouped
 - groups separated by an empty line
 - main group (the first one)
 - groups for individual entries in the archive
- length of lines max 65535
- end of lines
 - CR LF, LF, CR

MANIFEST.MF files

- main group
 - Manifest-Version
 - Created-By
 - Signature-Version
 - Class-Path
 - Main-Class
 - applications can be launched java -jar archive.jar
- other section
 - the first tuple

Name: path_to_the_entry_in_the_archive

Jar and Ant

- the task jar
 - parameters
 - destfile, basedir, includes, excludes, manifest
 - inner elements
 - manifest
 - examples

```
<jar destfile="${dist}/lib/app.jar"</pre>
       basedir="${build}/classes"
       excludes="**/Test.class"
<jar destfile="test.jar" basedir=".">
    <include name="build"/>
    <manifest>
      <attribute name="Built-By" value="${user.name}"/>
      <section name="common/class1.class">
        <attribute name="Sealed" value="false"/>
      </section>
    </manifest>
  </jar>
```

Jar and Maven

• maven-jar-plugin

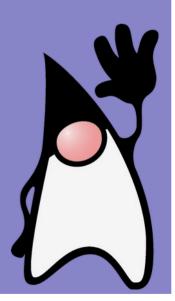

java.util.jar

- similar to java.util.zip
- JarInputStream, JarOutputStream
 - children of ZipInputStream and ZipOutputStream
 - JarlnputStream has the getManifest() method
- JarEntry
 - child of ZipEntry
 - obtaining attributes
- Manifest
 - the MANIFEST.MF file

Java

Modules

Modules

- a module
 - explicitely defines what is provided but also what is required

- why?
 - the *classpath* concept is "fragile"
 - no encapsulation

Modular apps – motivation

- why
 - applications get more complex
 - assembled from pieces
 - developed by distributed teams
 - complex dependencies
 - good architecture
 - know your dependencies
 - manage your dependencies

Module declaration

module-info.java

```
module com.foo.bar {
    requires com.foo.baz;
    exports com.foo.bar.alpha;
    exports com.foo.bar.beta;
}
```

- modular artifact
 - modular JAR JAR with module-info.class
 - a new format JMOD
 - a ZIP with classes, native code, configuration,...

Modules and JDK

- JDK std library modularized too
 - java.base always "required"

```
module java.base {
    exports java.io;
    exports java.lang;
    exports java.lang.annotation;
    exports java.lang.invoke;
    exports java.lang.module;
    exports java.lang.ref;
    exports java.lang.reflect;
    exports java.math;
    exports java.net;
```

Module readability & module path

When one module depends directly upon another

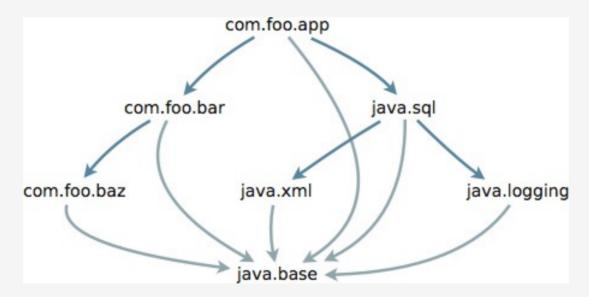

Module *reads* another module (or, equivalently, second module is *readable* by first)

- Module path equivalent to classpath
 - but for modules
 - -p, --module-path

Module graph

```
module com.foo.app {
    requires com.foo.bar;
    requires java.sql;
}
```

Compatibility with "old" Java

- Classpath still supported
 - in fact modules are "optional"
- Unnamed module
 - artefacts outside any module
 - "old" code
 - reads every other module
 - exports all of its packages to every other module

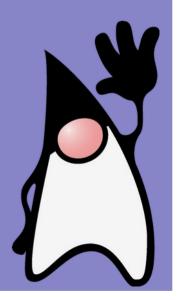

Modules

Java

Unit testing

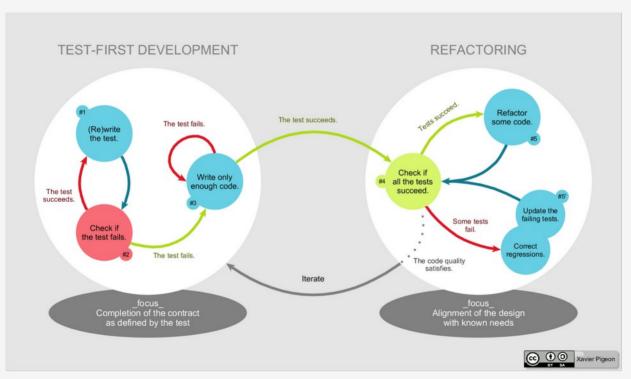

Introduction

- unit testing
 - testing "small" units of functionality
 - a unit independent on other ones
 - tests are separated
 - creating helper objects for tests
 - context
 - typically in OO languages
 - unit ~ method
 - ideally unit tests for all units in a program
 - typically in OO languages
 - for all public methods

Test-driven development

tests first

sourcej: https://commons.wikimedia.org/wiki/File:TDD_Global_Lifecycle.png#/media/File:TDD_Global_Lifecycle.png

JUnit

- support for unit testing in Java
- http://www.junit.org/
- usage based on annotations
 - older versions based on inheritance and naming conventions
- slightly different usage in different versions
 - 5, 4, 3

Usage

- test methods marked by the @Test annotation
- JUnit is run on a set of classes.
 - searches in them all @Test methods
 - executes them

•

- other annotations
 - @BeforeEach (@Before)
 - a method run before each test
 - intended for "environment" preparation
 - @AfterEach (@After)
 - a method run after each test
 - intended for "cleaning"
 - @BeforeAll (@BeforeClass)
 - a method run before all tests in the given class
 - @AfterAll (@AfterClass)
 - a method run after all tests in the given class

Java winter competer 2022/23

Example

```
public class SimpleTest {
   private Collection collection;
   @BeforeAll
   public static void oneTimeSetUp() {
      // one-time initialization code
   @AfterAll
   public static void oneTimeTearDown() {
     // one-time cleanup code
   @BeforeEach
   public void setUp() {
     collection = new ArrayList();
```

```
@AfterEach
public void tearDown() {
    collection.clear();
@Test
public void testEmptyCollection() {
    assertTrue(collection.isEmpty());
@Test
public void testOneItemCollection() {
    collection.add("itemA");
    assertEquals(1, collection.size());
```

Assert

- assertTrue
- assertFalse
- assertEquals
- assert...
 - static methods of org.junit.jupiter.api.Assertions (org.junit.Assert)
 - testing conditions in tests
 - test fails if assert... fails
 - assert...() throws AssertionError
- in general
 - test is successful if the method terminates regularly
 - test fails if the method throws an exception

Testing exceptions

how to test "correctly" thrown exceptions?

```
assertThrows(IndexOutOfBoundsException.class, () -> {
   new ArrayList<Object>().get(0);
});
```

in older versions

```
@Test(expected= IndexOutOfBoundsException.class) public void empty() {
   new ArrayList<Object>().get(0);
}
```

Running tests

from IDE

```
    from code

   org.junit.runner.JUnitCore.runClasses(TestClass1.class,...);

    from command line

   java -jar junit.jar -select-class TestClass1

    from Ant

 - the task junit
   <junit printsummary="yes" fork="yes" haltonfailure="yes">
     <formatter type="plain"/>
     <test name="my.test.TestCase"/>
   </junit>

    from Mayen

   mvn test
```

TestNG

- http://testng.org/
- inspired by JUnit
 - and later vice-versa
- slightly different set of features
 - originally
 - now, very similar
- basic usage is the same

Java

Reactive programming

Reactive programming (RP)

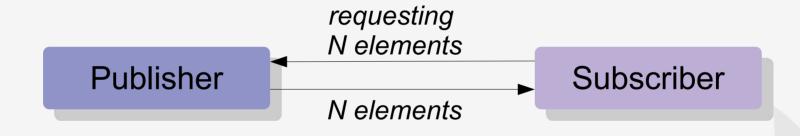

- data streams and propagating of changes in a program
- data changes are automatically propagated
- publisher-subscriber
- architectural pattern
- one of particular models for RP
- publisher publishes data
- subscriber asynchronously data consumes
- there can be processor between P and S transforming data

- why RP
- simpler code, more efficient, ...
- "an extension" of the stream API

Publisher-Subsriber in Java

- Flow API (Reactive streams)
- java.util.concurrent.Flow
 - since Java 9

• "a combination of iterator and observer patterns"

Flow API

```
@FunctionalInterface
public static interface Flow.Publisher<T> {
  public void subscribe(Flow.Subscriber<? super T> subscriber);
public static interface Flow.Subscriber<T> {
    public void on Subscribe (Flow. Subscription subscription);
    public void onNext(T item) ;
    public void onError(Throwable throwable);
    public void onComplete();
public static interface Flow.Subscription {
    public void request(long n);
    public void cancel();
public static interface Flow.Processor<T,R> extends Flow.Subscriber<T>, Flow.Publisher<R>
```

Flow API

- SubmissionPublisher
 - implements the Publisher interface
 - asynchronously publishes given data
 - the constructor without parameters
 - uses ForkJoinPool.commonPool()
 - other constructors an argument for an executor
 - methods
 - subscribe(Flow.Subscriber<? super T> subscriber)
 - submit(T item)
 - ...

Observer pattern

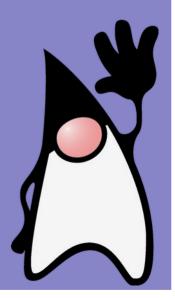

- an object (observer) "observes" another object (observable) if the other object changes, it notifies all its observers
 - java.util.Observer
 - java.util.Observable
 - warning Deprecated since Java 9 (replaced by Flow)

- usage
 - UI
 - Observable UI components
 - Observer reactions to UI events

Java

More about threads

ThreadLocal

- own copy for each thread
- typically used as static fields

methods

```
T get()
protected T initialValue()
void remove()
void set(T value)
static <S> ThreadLocal<S> withInitial(Supplier<? extends S> supplier)
```
